

**METHOD OF SUPPORTING MULTIPLE SERVICE LEVELS
IN A WIRELESS NETWORK**

Abstract of the Invention

5 A wireless data network distinguishes among different users connected to the network
and associates each user with a service class that offers a selected level of service. The base
station in the network queries the user for its unique user identification code and accesses a
database linking user identification codes with their corresponding services classes. The
network then controls the service level given to that user based on the service class associated
10 with the user identification code. The user identification code can be sent to the network via
existing fields in current standards.
